Cognitive impairment in depressed elderly patients: results of a 4-year follow-up study. Cognitive impairment was investigated in 751 depressed elderly patients at baseline, at 4-year follow-up, and at 2 and 3 years after baseline. Baseline cognitive impairment was associated with the following subsequent outcome variables at 2 years: increased frequency of major depression, additional depressive symptoms, suicide attempt, and early readmission to a psychiatric hospital. Baseline impairment in sustained attention predicted all of these outcomes and in addition was associated with increased early readmission at the 3-year follow-up. Baseline impairment in concentration predicted readmission at both 2 and 3 years, and in addition was associated with increased suicidal ideation at the 4-year follow-up. Baseline impairment in memory function was associated with major depression at the 4-year follow-up. Improvement in cognitive function was associated with the recovery from depression at the 4-year follow-up. Thus, cognitive impairment at baseline can be used as a predictor of poor long-term outcome in elderly depressed patients. The recovery of cognitive function, however, was observed in only 17% of the patients.
